# DG Method for Burgers' Equation

# Advantages of the Discontinuous Galerkin (DG) Method

- Discontinuous Galerkin (DG) methods are a class of finite element methods using completely discontinuous piecewise polynomial spaces as the basis
- DG methods are high-order schemes, which allow for a coarse spatial mesh to achieve the same accuracy,
- DG methods achieve local conservativity, easily handle complicated geometries and boundary conditions
- Allow flexibility for h-p adaptivity, efficient parallel implementation, easy coordination with finite volume techniques
- DG methods have attracted attention for high performance computing due to high computational intensity and less data communication

# DG Method for Burgers' Equation

Suppose we wish to solve the following IBVP

$$\begin{cases} u_t + \left(\frac{u^2}{2}\right)_x = 0 & (x, t) \in (0, L) \times (0, T) \\ u(x, 0) = u_0(x) & (x, t) \in (0, L) \times \{0\} \\ u(0, t) = u(L, t) \end{cases}$$

# DG Method for Burgers' Equation

Suppose we wish to solve the following IVP

$$\begin{cases} u_t + \left(\frac{u^2}{2}\right)_x = 0 & (x, t) \in (0, L) \times (0, T) \\ u(x, 0) = u_0(x) & (x, t) \in (0, L) \times \{0\} \\ u(0, t) = u(L, t) \end{cases}$$

- Partition spatial interval  $(a, b)$  with nodes  $\{x_{j+1/2}\}_{j=0}^N$ , and set  $I_j = (x_{j-1/2}, x_{j+1/2})$
  - $\Delta x_j = x_{j+1/2} - x_{j-1/2}$  for  $j = 1, \dots, N$
  - For simplicity, take the mesh to be uniform:  $\Delta x = \text{constant.}$

Discontinuous Galerkin (DG) Method

## DG Method for Burgers' Equation (cont.)

- Denote  $u_h$  as the approximate solution.

Multiplication by an arbitrary test function,  $\phi_h$ , and integrating by parts,

$$\int_{I_j} (u_h)_t \phi_h \, dx + \int_{I_j} \left( \frac{u_h^2}{2} \right)_x \phi_h \, dx = 0,$$

$$\int (u_h)_t \phi_h \, dx - \int \left( \frac{u_h^2}{2} \right) (\phi_h)_x - \sum_{j=1}^N \left( \left( \frac{1}{2} \widehat{u_h^2} \right) [\phi_h] \right)_{j+1/2} = 0,$$

where  $\int = \sum_{j=1}^N \int_{I_j}$ ,  $\widehat{u_h^2}$  is the numerical flux, and  $[\phi_h] = \phi_h^+ - \phi_h^-$ .

## DG Method for Burgers' Equation (cont.)

- All that remains is determine how we should define  $\widehat{u}_h^2$
  - From the method of characteristics, we know how information propagates over time, that is in the direction of the characteristics
  - Therefore, we choose what is called the “upwind flux,” and take  $\widehat{u}_h^2 = (u_h^-)^2$ , where we take the value at the cell boundary to be from the left side
  - In general, the choice of numerical flux is more difficult

Discontinuous Galerkin (DG) Method

# Results

For the numerical test, we will solve the problem

$$\begin{cases} u_t + \left( \frac{u^2}{2} \right)_x = 0 & (x, t) \in (0, 1) \times (0, T) \\ u(x, 0) = 2 + \sin(2\pi x) & (x, t) \in (0, 1) \times \{0\} \\ u(0, t) = u(1, t) \end{cases}$$

where  $T$  is the final time.

# DG Method for the BBM-System

# Coupled BBM-system in Conservation Form

The coupled BBM-system given by

$$\begin{cases} \eta_t + u_x + (\eta u)_x - \frac{1}{6}\eta_{xxt} = 0, \\ u_t + \eta_x + uu_x - \frac{1}{6}u_{xxt} = 0. \end{cases}$$

# Coupled BBM-system in Conservation Form

The coupled BBM-system given by

$$\begin{cases} \eta_t + u_x + (\eta u)_x - \frac{1}{6}\eta_{xxt} = 0, \\ u_t + \eta_x + uu_x - \frac{1}{6}u_{xxt} = 0. \end{cases}$$

We can write the above system in a conservation form

$$\begin{cases} \left(\eta - \frac{1}{6}\eta_{xx}\right)_t + (u + (\eta u))_x = 0, \\ \left(u - \frac{1}{6}u_{xx}\right)_t + \left(\eta + \frac{u^2}{2}\right)_x = 0. \end{cases}$$

# Coupled BBM-system as a system of first order equations

We can rewrite the coupled-BBM system into a system of first order equations as the following

$$w_t + (\eta + q)_x = 0$$

$$w = u - \frac{1}{6}r_x$$

$$r = u_x$$

$$q = \frac{1}{2}u^2$$

$$v_t + (u + p)_x = 0$$

$$v = \eta - \frac{1}{6}s_x$$

$$s = \eta_x$$

$$p = \eta u$$

# DG Formulation

The DG method is formulated as follows: for any test functions

$\phi_h, \psi_h, \varphi_h, \zeta_h, \rho_h, \theta_h, \xi_h, \vartheta_h \in V_h^k$ , find

$w_h, v_h, u_h, \eta_h, r_h, s_h, p_h, q_h \in V_h^k$  such that

$$\int (w_h)_t \phi_h \, dx - \int (\eta_h + q_h) (\phi_h)_x \, dx - \sum_{j=1}^N ((\tilde{\eta}_h + \widehat{q}_h)[\phi_h])_{j+\frac{1}{2}} = 0$$

$$\int w_h \psi_h \, dx - \int u_h (\psi_h)_x \, dx - \frac{1}{6} \int r_h (\psi_h)_x \, dx - \frac{1}{6} \sum_{j=1}^N (\widehat{r}_h[\psi_h])_{j+\frac{1}{2}} = 0$$

$$\int r_h \varphi_h \, dx + \int u_h (\varphi_h)_x \, dx + \sum_{j=1}^N (\widehat{u}_h[\varphi_h])_{j+\frac{1}{2}} = 0$$

$$\int q_h \zeta_h \, dx - \int \left( \frac{1}{2} (u_h)^2 \right) \zeta_h \, dx = 0$$

## DG Formulation (cont.)

$$\int (v_h)_t \rho_h \, dx - \int (u_h + p_h) (\rho_h)_x \, dx - \sum_{j=1}^N ((\tilde{u}_h + \widehat{p_h}) [\rho_h])_{j+\frac{1}{2}} = 0$$

$$\int v_h \theta_h \, dx - \int \eta_h \theta_h \, dx - \frac{1}{6} \int s_h (\theta_h)_x \, dx - \frac{1}{6} \sum_{j=1}^N (\widehat{s_h} [\theta_h])_{j+\frac{1}{2}} = 0$$

$$\int s_h \xi_h \, dx + \int \eta_h (\xi_h)_x \, dx + \sum_{j=1}^N (\widehat{\eta_h} [\xi_h])_{j+\frac{1}{2}} = 0$$

$$\int p_h \vartheta_h \, dx - \int (\eta_h u_h) \vartheta_h \, dx = 0$$

# Choice of Numerical Flux

We investigate two different choices of numerical flux, depending on what properties we wish to preserve. First is the *alternating flux*

$$\begin{cases} \widehat{u_h} = u_h^+, \\ \widehat{\eta_h} = \eta_h^- . \end{cases} \quad \begin{cases} \widetilde{u_h} + \widehat{p_h} = u_h^+ + p_h^+, \\ \widetilde{\eta_h} + \widehat{q_h} = \eta_h^- + q_h^-, \\ \widehat{r_h} = r_h^-, \\ \widehat{s_h} = s_h^+. \end{cases}$$

- Choice of flux follows from trying to cancel out the boundary terms that arise in the DG formulation

# Choice of Numerical Flux

We investigate two different choices of numerical flux, depending on what properties we wish to preserve. First is the *alternating flux*

$$\begin{cases} \widehat{u_h} = u_h^+, \\ \widehat{\eta_h} = \eta_h^- . \end{cases} \quad \begin{cases} \widetilde{u_h} + \widehat{p_h} = u_h^+ + p_h^+, \\ \widetilde{\eta_h} + \widehat{q_h} = \eta_h^- + q_h^-, \\ \widehat{r_h} = r_h^-, \\ \widehat{s_h} = s_h^+. \end{cases}$$

- Choice of flux follows from trying to cancel out the boundary terms that arise in the DG formulation
- Choosing  $u_h, \eta_h$ , and  $p_h, q_h$ , and  $r_h, s_h$  from opposite sides, the summation terms, and some of the integrals cancel out from integration by parts

# Choice of Numerical Flux

We investigate two different choices of numerical flux, depending on what properties we wish to preserve. First is the *alternating flux*

$$\begin{cases} \widehat{u_h} = u_h^+, \\ \widehat{\eta_h} = \eta_h^- . \end{cases} \quad \begin{cases} \widetilde{u_h} + \widehat{p_h} = u_h^+ + p_h^+, \\ \widetilde{\eta_h} + \widehat{q_h} = \eta_h^- + q_h^-, \\ \widehat{r_h} = r_h^-, \\ \widehat{s_h} = s_h^+. \end{cases}$$

- Choice of flux follows from trying cancel out the boundary terms that arise in the DG formulation
- Choosing  $u_h, \eta_h$ , and  $p_h, q_h$ , and  $r_h, s_h$  from opposite sides, the summation terms, and some of the integrals cancel out from integration by parts
- Remaining terms give the energy which is conserved by the method

# Stability Theorem

## Theorem (Stability)

*For the choice of alternating flux, the (continuous) energy,  $\mathcal{E}_h(t)$ , is conserved by the DG method, i.e.*

$$\frac{d}{dt} \mathcal{E}_h(t) = \frac{d}{dt} \int_I (\eta_h^2 + (1 + \eta_h) u_h^2) dx = 0$$

*for all time.*

# Stability Theorem

## Theorem (Stability)

*For the choice of alternating flux, the (continuous) energy,  $\mathcal{E}_h(t)$ , is conserved by the DG method, i.e.*

$$\frac{d}{dt}\mathcal{E}_h(t) = \frac{d}{dt} \int_I (\eta_h^2 + (1 + \eta_h)u_h^2) dx = 0$$

*for all time.*

The proof follows from choosing the alternating flux from the previous slides. Boundary terms can be eliminated by integration by parts identities. The proof is similar to that of the energy conservation theorem found in *Chen, Liu (2012)* at the PDE level.

## Choice of Numerical Flux

Second, is the upwind flux which introduces numerical dissipation, and has the choices of

$$\begin{cases} \widetilde{u_h} = \{u_h\} - \frac{1}{2}[\eta_h], \\ \widetilde{\eta_h} = \{\eta_h\} - \frac{1}{2}[u_h]. \end{cases} \quad \begin{cases} \widehat{q_h} = \{q_h\} - \frac{1}{2}[p_h], \\ \widehat{p_h} = \{p_h\} - \frac{1}{2}[q_h]. \end{cases}$$

$$\begin{cases} \widetilde{(u_h)_t} = \{(u_h)_t\} + \frac{1}{2}[(\eta_h)_t], \\ \widetilde{(\eta_h)_t} = \{(\eta_h)_t\} + \frac{1}{2}[(u_h)_t]. \end{cases} \quad \begin{cases} \widetilde{(r_h)_t} = \{(r_h)_t\} - \frac{1}{2}[(s_h)_t], \\ \widetilde{(s_h)_t} = \{(s_h)_t\} - \frac{1}{2}[(r_h)_t]. \end{cases}$$

- Notation:  $\{u_h\} = \frac{u_h^+ + u_h^-}{2}$  and  $[u_h] = u_h^+ - u_h^-$
- Choice of flux follows from eliminating the third derivative term to get a system of hyperbolic conservation laws
- Upwind flux is the standard choice for this type of system
- Chosen to add numerical dissipation to the system

# Energy Dissipation Theorem

## Theorem (Energy Dissipation)

*For the choice of upwind flux, the energy,  $\mathcal{E}_h(t)$ , satisfies*

$$\frac{d}{dt}\mathcal{E}_h(t) = \frac{d}{dt} \int_I (\eta_h^2 + (1 + \eta_h)u_h^2) dx \leq 0$$

*with the DG method.*

# Energy Dissipation Theorem

## Theorem (Energy Dissipation)

*For the choice of upwind flux, the energy,  $\mathcal{E}_h(t)$ , satisfies*

$$\frac{d}{dt}\mathcal{E}_h(t) = \frac{d}{dt} \int_I (\eta_h^2 + (1 + \eta_h)u_h^2) dx \leq 0$$

*with the DG method.*

The proof follows similar to the previous stability proof, except we choose the upwind flux choices from previous slides. With this choice, boundary terms from the DG method are still present. These terms can be bounded by a routine application of Young's inequality to get the energy estimate.

  - ③ Computationally expensive as this is an implicit method

# Remaining Theoretical Work

- The error estimate proof of the DG method for the single BBM equation case completed. We have proved the suboptimal error estimate.

# Remaining Theoretical Work

- The error estimate proof of the DG method for the single BBM equation case completed. We have proved the suboptimal error estimate.
- For the coupled BBM system, we would also like to establish the sub-optimal error estimate

$$\|u - u_h\| \leq Ch^{k+\frac{1}{2}}$$

where  $u$  is the true solution,  $u_h$  is the DG approximation, and  $k$  is the degree of the piecewise polynomial space.

## Remaining Theoretical Work

- The error estimate proof of the DG method for the single BBM equation case completed. We have proved the suboptimal error estimate.
- For the coupled BBM system, we would also like to establish the sub-optimal error estimate

$$\|u - u_h\| \leq Ch^{k+\frac{1}{2}}$$

where  $u$  is the true solution,  $u_h$  is the DG approximation, and  $k$  is the degree of the piecewise polynomial space.

- Difficulty arises in this proof due to the nonlinear terms present and the coupled nature of the system.

## Numerical Results

## Solutions to the BBM-system (Exact Traveling Wave Solution)

- Chen (1998), the exact traveling wave solution to the BBM-system is

$$u(x, t) = 3k \operatorname{sech}^2 \left( \frac{3}{\sqrt{10}}(x - kt - x_0) \right),$$

$$\eta(x, t) =$$

$$\frac{15}{4} \left( -2 + \cosh \left( 3\sqrt{\frac{2}{5}}(x - kt - x_0) \right) \right) \operatorname{sech}^4 \left( \frac{3}{\sqrt{10}}(x - kt - x_0) \right)$$

where  $k = \pm \frac{5}{2}$ , and  $x_0$  is the  $x$  value where the center of the wave is located

## Numerical Results

## Solutions to the BBM-system (Approximate Solitary Wave Solution)

- *Alazman, et. al (2006)*, the coupled BBM-system has solitary wave solutions similar to the single BBM equation given by

$$v_t + v_x + \frac{3}{2}\epsilon vv_x - \frac{1}{6}\epsilon v_{xxt} = 0,$$

## Numerical Results

## Solutions to the BBM-system (Approximate Solitary Wave Solution)

- Alazman, et. al (2006), the coupled BBM-system has solitary wave solutions similar to the single BBM equation given by

$$v_t + v_x + \frac{3}{2}\epsilon vv_x - \frac{1}{6}\epsilon v_{xxt} = 0,$$

where  $\epsilon$  represents the ratio of the maximum wave amplitude to the undisturbed depth of the liquid.

- The exact traveling wave solution to the single BBM equation is

$$v(x, t) = \operatorname{sech}^2\left(\frac{1}{2}\sqrt{\frac{3}{\kappa}}(x - \kappa t - x_0)\right),$$

where  $\kappa = 1 + \epsilon/2$ .

## Numerical Results

## Solutions to the BBM-system (Approximate Solitary Wave Solution)

- An *approximate* solitary wave can be constructed using the following initial condition with the coupled BBM-system

$$\eta(x, 0) = v(x, 0),$$

$$u(x, 0) = v(x, 0) - \frac{1}{4}\epsilon v(x, 0)^2,$$

where  $v(x, t)$  is the exact traveling solution to the single BBM-equation

## Numerical Results

## Solutions to the BBM-system (Approximate Solitary Wave Solution)

- An *approximate* solitary wave can be constructed using the following initial condition with the coupled BBM-system

$$\eta(x, 0) = v(x, 0),$$

$$u(x, 0) = v(x, 0) - \frac{1}{4}\epsilon v(x, 0)^2,$$

where  $v(x, t)$  is the exact traveling solution to the single BBM-equation

- Compare the single BBM solution to the coupled-BBM system with given initial data

## Numerical Results

## Solutions to the BBM-system (Approximate Solitary Wave Solution)

- An *approximate* solitary wave can be constructed using the following initial condition with the coupled BBM-system

$$\eta(x, 0) = v(x, 0),$$

$$u(x, 0) = v(x, 0) - \frac{1}{4}\epsilon v(x, 0)^2,$$

where  $v(x, t)$  is the exact traveling solution to the single BBM-equation

- Compare the single BBM solution to the coupled-BBM system with given initial data
- Approximate solitary wave for the coupled-BBM system,  $\eta(x, t)$ , is accurate to  $\mathcal{O}\left(\frac{1}{\epsilon}\right)$  in time

# Solitary Wave Generation Test

For the solitary wave generation test, we start with a first order approximation to the traveling wave solution that was used in the mesh refinement, and long time tests. The initial condition is given by

$$\eta(x, 0) = \eta_0 \operatorname{sech}^2 \left( \frac{1}{2} \sqrt{\frac{3\eta_0}{k}} (x - x_0) \right),$$
$$u(x, 0) = \eta(x, 0) - \frac{1}{4} \eta(x, 0)^2,$$

where  $\eta_0 = 0.8$  is the peak height for  $\eta(x, 0)$ , and  $x_0 = 20$ .

## Numerical Results

# Solitary Wave Generation Test

For the solitary wave generation test, we start with a first order approximation to the traveling wave solution that was used in the mesh refinement, and long time tests. The initial condition is given by

$$\eta(x, 0) = \eta_0 \operatorname{sech}^2 \left( \frac{1}{2} \sqrt{\frac{3\eta_0}{k}} (x - x_0) \right),$$
$$u(x, 0) = \eta(x, 0) - \frac{1}{4} \eta(x, 0)^2,$$

where  $\eta_0 = 0.8$  is the peak height for  $\eta(x, 0)$ , and  $x_0 = 20$ .

The wave is evolved over the long domain, then “filtered”, and reset back to the left hand side of the domain. The process is repeated until dispersive tails are “small.”

Burgers' Equation with Stochastic Inputs

## Burgers' Equation with Stochastic Inputs Problem Statement

Burgers' equation can be stated as

$$\begin{cases} u_t + uu_x = 0 & \text{for } (x, t) \in [a, b] \times [0, T] \\ u(x, 0) = u_0(x) & \text{for } (x, t) \in [a, b] \times \{0\} \end{cases}$$

Burgers' Equation with Stochastic Inputs

## Burgers' Equation with Stochastic Inputs Problem Statement

Burgers' equation can be stated as

$$\begin{cases} u_t + uu_x = 0 & \text{for } (x, t) \in [a, b] \times [0, T] \\ u(x, 0) = u_0(x) & \text{for } (x, t) \in [a, b] \times \{0\} \end{cases}$$

We will consider the situation when the initial condition has a stochastic component. The problem is stated as

$$\begin{cases} u_t + uu_x = 0 & \text{for } (x, t, \xi) \in [0, 3] \times [0, T^* - \epsilon] \times \mathbb{R} \\ u(x, 0, \xi) = u_0(x, \xi) & \text{for } (x, t, \xi) \in [0, 3] \times \{0\} \times \mathbb{R} \end{cases}$$

Burgers' Equation with Stochastic Inputs

# Burgers' Equation with Stochastic Inputs Problem Statement

Burgers' equation can be stated as

$$\begin{cases} u_t + uu_x = 0 & \text{for } (x, t) \in [a, b] \times [0, T] \\ u(x, 0) = u_0(x) & \text{for } (x, t) \in [a, b] \times \{0\} \end{cases}$$

We will consider the situation when the initial condition has a stochastic component. The problem is stated as

$$\begin{cases} u_t + uu_x = 0 & \text{for } (x, t, \xi) \in [0, 3] \times [0, T^* - \epsilon] \times \mathbb{R} \\ u(x, 0, \xi) = u_0(x, \xi) & \text{for } (x, t, \xi) \in [0, 3] \times \{0\} \times \mathbb{R} \end{cases}$$

where the solution,  $u(x, t, \xi)$  is a function of the random parameter  $\xi \sim \mathcal{U}(-1, 1)$ . We run the code up to time  $T^* - \epsilon$  which is the time just before the shock develops.

Burgers' Equation with Stochastic Inputs

## Problem Statement (cont.)

For the stochastic initial condition,  $u_0(x, \xi)$ , we have the following formula

$$u_0(x, \xi) = K_0 1_{[0, x_0]}(x - \sigma \xi) + K_1 1_{[x_1, 3]}(x - \sigma \xi) + \\ \left( \frac{K_1 - K_0}{x_1 - x_0} (x - \sigma \xi) - \frac{K_0 x_1 - K_1 x_0}{x_1 - x_0} \right) 1_{[x_0, x_1]}(x - \sigma \xi)$$

where  $1$  is the characteristic function, and  $\sigma$  is the weight for the stochastic component.

## Problem Statement (cont.)

For the stochastic initial condition,  $u_0(x, \xi)$ , we have the following formula

$$u_0(x, \xi) = K_0 1_{[0, x_0]}(x - \sigma \xi) + K_1 1_{[x_1, 3]}(x - \sigma \xi) + \\ \left( \frac{K_1 - K_0}{x_1 - x_0} (x - \sigma \xi) - \frac{K_0 x_1 - K_1 x_0}{x_1 - x_0} \right) 1_{[x_0, x_1]}(x - \sigma \xi)$$

where  $\mathbf{1}$  is the characteristic function, and  $\sigma$  is the weight for the stochastic component.

The values of the other components are  $K_0 = 1.2$ ,  $K_1 = 0.2$ ,  $x_0 = 0.5$ ,  $x_1 = 1.5$ , and  $\sigma = 0.01$ .

## gPC Expansion

To begin, we assume that the solution to the problem can be written as the spectral expansion

$$u(x, t, \xi) = \sum_{i=0}^{\infty} u_i(x, t) \Phi_i(\xi),$$

where the  $\Phi_i(\xi)$  are the stochastic basis elements

## gPC Expansion

To begin, we assume that the solution to the problem can be written as the spectral expansion

$$u(x, t, \xi) = \sum_{i=0}^{\infty} u_i(x, t) \Phi_i(\xi),$$

where the  $\Phi_i(\xi)$  are the stochastic basis elements

Denote the inner product over the probability space to be

$$\langle u, v \rangle = \int_{\Omega} uv f(\xi) \, d\xi.$$

where  $f(\xi) = \frac{1}{2}$ , the probability density function for  $\mathcal{U}(-1, 1)$ .

gPC with DG Method

# gPC Expansion of Burgers' Equation

To find the expansion of Burgers' Equation, we substitute the spectral expansion into the PDE to get

$$u_t + uu_x = 0$$

$$\sum_{i=0}^{\infty} \frac{\partial u_i}{\partial t} \Phi_i(\xi) + \left( \sum_{j=0}^{\infty} u_j \Phi_j(\xi) \right) \left( \sum_{i=0}^{\infty} \frac{\partial u_i}{\partial x} \Phi_i(\xi) \right) = 0$$

gPC with DG Method

## gPC Expansion of Burgers' Equation

To find the expansion of Burgers' Equation, we substitute the spectral expansion into the PDE to get

$$u_t + uu_x = 0$$

Now by multiplying through by the basis functions,  $\Phi_k(\xi)$  and integrating over the probability space  $\Omega$ , we have

$$\frac{\partial u_k}{\partial t} \langle \Phi_k, \Phi_k \rangle + \sum_{i=0}^M \sum_{j=0}^M u_i \frac{\partial u_j}{\partial x} \langle \Phi_i \Phi_j, \Phi_k \rangle = 0 \quad \text{for } k = 0, 1, \dots, M$$

where we have truncated the expansion to  $M + 1$  terms.

## gPC Expansion of Burgers' Equation

From the previous slide,

$$\frac{\partial u_k}{\partial t} \langle \Phi_k, \Phi_k \rangle + \sum_{i=0}^M \sum_{j=0}^M u_i \frac{\partial u_j}{\partial x} \langle \Phi_i \Phi_j, \Phi_k \rangle = 0 \quad \text{for } k = 0, 1, \dots, M$$

# gPC Expansion of Burgers' Equation

From the previous slide,

$$\frac{\partial u_k}{\partial t} \langle \Phi_k, \Phi_k \rangle + \sum_{i=0}^M \sum_{j=0}^M u_i \frac{\partial u_j}{\partial x} \langle \Phi_i \Phi_j, \Phi_k \rangle = 0 \quad \text{for } k = 0, 1, \dots, M$$

We can also write the above in conservative form

$$\frac{\partial u_k}{\partial t} \langle \Phi_k, \Phi_k \rangle + \frac{1}{2} \frac{\partial}{\partial x} \sum_{i=0}^M \sum_{j=0}^M u_i u_j \langle \Phi_i \Phi_j, \Phi_k \rangle = 0 \quad \text{for } k = 0, 1, \dots, M$$

gPC with DG Method

# gPC Solution to Burgers' Equation

The solution then can be written as follows:

$$u(x, t, \xi) = \sum_{i=0}^N u_i(x, t) \Phi_i(\xi),$$

$$u_i(x, t) = \sum_{j=0}^k a_{i,j}(t) \psi_j(x),$$

where the  $\Phi_i(\xi)$  are the Legendre polynomials,  $\psi_j(x) \in V_h^k(I_j)$ , and the  $a_{i,j}$  are coefficient weights at a any time  $t$ .

# gPC Solution to Burgers' Equation

The solution then can be written as follows:

$$u(x, t, \xi) = \sum_{i=0}^N u_i(x, t) \Phi_i(\xi),$$

$$u_i(x, t) = \sum_{j=0}^k a_{i,j}(t) \psi_j(x),$$

where the  $\Phi_i(\xi)$  are the Legendre polynomials,  $\psi_j(x) \in V_h^k(I_j)$ , and the  $a_{i,j}$  are coefficient weights at any time  $t$ .

Therefore, each  $u_i(x, t)$  is a polynomial of degree  $k$  from the DG method, with  $N + 1$  such equations. The numerical solution is thus a finite sum of products of polynomials in  $x$  and  $\xi$ .

gPC with DG Method

# Implementation

In order to solve the stochastic problem, we have to solve the system of conservation laws on the previous slide. First, we have to write the initial condition in terms of the gPC basis

$$u_0(x, \xi) = \sum_{i=0}^1 \tilde{u}_i(x) \Phi_i(\xi),$$

where

$$\tilde{u}_i(x) = \langle \Phi_i(\xi), u_0(x, \xi) \rangle = \frac{1}{\sqrt{2\pi}} \int_{\Omega} \Phi_i(\xi) u_0(x, \xi) e^{\frac{-\xi^2}{2}} d\xi$$

# Implementation

In order to compute the integral above, we use Gauss-Hermite quadrature, which approximates

$$\frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} g(\xi) e^{\frac{-\xi^2}{2}} d\xi \approx \frac{1}{\sqrt{\pi}} \sum_{i=1}^n \omega_i g(\sqrt{2}x_i)$$

where we used a change of variables  $x = \frac{\xi}{\sqrt{2}}$ , and  $\omega_i$  and  $x_i$  are the Gauss-Hermite quadrature weights and nodes over  $[-\infty, \infty]$ .

# Implementation

In order to compute the integral above, we use Gauss-Hermite quadrature, which approximates

$$\frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} g(\xi) e^{\frac{-\xi^2}{2}} d\xi \approx \frac{1}{\sqrt{\pi}} \sum_{i=1}^n \omega_i g(\sqrt{2}x_i)$$

where we used a change of variables  $x = \frac{\xi}{\sqrt{2}}$ , and  $\omega_i$  and  $x_i$  are the Gauss-Hermite quadrature weights and nodes over  $[-\infty, \infty]$ . Another change of variables is required on the initial condition

$$u_0(x, \xi) = K_0 1_{[0, x_0]}(x - \sigma\xi) + K_1 1_{[x_1, 3]}(x - \sigma\xi) + \\ \left( \frac{K_1 - K_0}{x_1 - x_0}(x - \sigma\xi) - \frac{K_0 x_1 - K_1 x_0}{x_1 - x_0} \right) 1_{[x_0, x_1]}(x - \sigma\xi)$$

DG Method

DG for BBM  
oooooooooooooooooooooooooooo

Stochastic  
oooooooo●oooooooo

gPC with DG Method

# Implementation

This is due to the fact we need to integrate out the stochastic term  $\xi$ , so the IC becomes

$$u_0(x, \xi) = K_0 1_{[\frac{x-x_0}{\sigma}, \frac{x}{\sigma}]}(\xi) + K_1 1_{[\frac{x-3}{\sigma}, \frac{x-x_1}{\sigma}]}(\xi) + \\ \left( \frac{K_1 - K_0}{x_1 - x_0}(x - \sigma\xi) - \frac{K_0 x_1 - K_1 x_0}{x_1 - x_0} \right) 1_{[\frac{x-x_1}{\sigma}, \frac{x-x_0}{\sigma}]}(\xi)$$

# Implementation

This is due to the fact we need to integrate out the stochastic term  $\xi$ , so the IC becomes

$$u_0(x, \xi) = K_0 1_{[\frac{x-x_0}{\sigma}, \frac{x}{\sigma}]}(\xi) + K_1 1_{[\frac{x-3}{\sigma}, \frac{x-x_1}{\sigma}]}(\xi) + \\ \left( \frac{K_1 - K_0}{x_1 - x_0}(x - \sigma\xi) - \frac{K_0 x_1 - K_1 x_0}{x_1 - x_0} \right) 1_{[\frac{x-x_1}{\sigma}, \frac{x-x_0}{\sigma}]}(\xi)$$

In the above, the values of  $x$  are taken to be the quadrature points we will use in the next step for the DG method, so the now have the initial condition written in the form

$$u_0(x, \xi) = \sum_{i=0}^1 \tilde{u}_i(x) \Phi_i(\xi),$$

gPC with DG Method

# DG Implementation

We now return to solve the deterministic system

$$u_t + \frac{\partial}{\partial x} f(u) = 0, \quad f(u) = \frac{1}{2} A(u) u$$

where

$$\frac{1}{2} A(u) u = \begin{bmatrix} \frac{1}{2} u_0^2 + \frac{1}{2} u_1^2 \\ u_0 u_1 \end{bmatrix}$$

gPC with DG Method

# DG Implementation

We now return to solve the deterministic system

$$u_t + \frac{\partial}{\partial x} f(u) = 0, \quad f(u) = \frac{1}{2} A(u) u$$

where

$$\frac{1}{2} A(u) u = \begin{bmatrix} \frac{1}{2} u_0^2 + \frac{1}{2} u_1^2 \\ u_0 u_1 \end{bmatrix}$$

In system form, we have

$$\frac{\partial u_0}{\partial t} + \frac{\partial}{\partial x} \left( \frac{1}{2} u_0^2 + \frac{1}{2} u_1^2 \right) = 0$$

$$\frac{\partial u_1}{\partial t} + \frac{\partial}{\partial x} (u_0 u_1) = 0$$

# DG Implementation

The weak formulation of the system is given by the following

$$\int_0^3 (u_0)_t \phi \, dx + \int_0^3 \left( \frac{1}{2} u_0^2 + \frac{1}{2} u_1^2 \right)_x \phi \, dx = 0$$

$$\int_0^3 (u_1)_t \psi \, dx + \int_0^3 (u_0 u_1)_x \psi \, dx = 0,$$

# DG Implementation

The weak formulation of the system is given by the following

$$\int_0^3 (u_0)_t \phi \, dx + \int_0^3 \left( \frac{1}{2} u_0^2 + \frac{1}{2} u_1^2 \right)_x \phi \, dx = 0$$

$$\int_0^3 (u_1)_t \psi \, dx + \int_0^3 (u_0 u_1)_x \psi \, dx = 0,$$

For the DG formulation, we choose test functions  $\phi_h, \psi_h \in V_h^k$ ,  
and search for  $(u_0)_h, (u_1)_h \in V_h^k$  such that

$$\begin{aligned} & \int ((u_0)_h)_t \phi_h \, dx - \int \left( \frac{1}{2} ((u_0)_h)^2 + \frac{1}{2} ((u_1)_h)^2 \right) (\phi_h)_x \, dx \\ & \quad - \sum_{j=1}^N \left( \left( \frac{1}{2} (\widehat{(u_0)_h})^2 + \frac{1}{2} (\widehat{(u_1)_h})^2 \right) [\phi_h] \right)_{j+\frac{1}{2}} = 0, \end{aligned}$$

$$\int ((u_1)_h)_t \psi_h \, dx - \int (p_h) (\psi_h)_x \, dx - \sum_{j=1}^N (\widehat{p}_h [\psi_h])_{j+\frac{1}{2}} = 0$$
